Partial fractions

Def: The function $P_m(x) = a_m x^m + a_{m-1} x^{m-1} + \dots + a_1 x + a_0$ is called a polynomial of degree m , as $a_m \neq 0$

The function $Q(x) = \frac{P_m(x)}{q_m(x)}$ is called a **rational function**.
 (where $P_m(x)$ is the **numerator** and $q_m(x)$ is the **denominator**)

$$\frac{2}{x+1} - \frac{3}{x+2} = \frac{2(x+2) - 3(x+1)}{(x+1)(x+2)} = \frac{1-x}{(x+1)(x+2)}$$

To put any **fraction** in the form of partial follow these steps:

1- Make sure that the degree of the ~~numerator~~ ^{lower} numerator is ~~higher~~ then the degree of the denominator

2- Analyze $q_m(x)$. The roots of " q " are one of four cases

Case 1: Simple roots of 1st degree.

$$Q(x) = \frac{P_m(x)}{(\dots)(x-a)} = \dots + \frac{a_1}{x-a}$$

$$a_1 = \lim_{x \rightarrow a} (x-a) Q(x) = \frac{P_m(x)}{(\dots)}$$

Ex: Factorize $\frac{x^2+1}{(x+2)(x-1)}$

$$\begin{array}{r} x^2+x-2 \overline{) x^2+1} \\ \underline{x^2+x-2} \\ -x+3 \end{array}$$

$$Q(x) = 1 + \frac{3-x}{x^2+x-2} = 1 + \frac{3-x}{(x+1)(x+2)} = 1 + \frac{a}{x+1} - \frac{b}{x+2}$$

$$a = \lim_{x \rightarrow -1} \frac{3-x}{x+2} = \frac{2}{3}$$

$$b = \lim_{x \rightarrow -2} \frac{3-x}{x-1} = \frac{5}{-3}$$

$$Q(x) = 1 + \frac{2}{3(x-1)} + \frac{5}{3(x+2)}$$

#

Case 2: Repeated real roots.

$$Q(x) = \frac{P_m(x)}{(x-a)^K} = \dots + \frac{a_K}{(x-a)^K} + \frac{a_{K-1}}{(x-a)^{K-1}} + \dots + \frac{a_1}{(x-a)}$$

Where: $a_K \rightarrow$ By direct method

$a_{K-1} \dots a_1 \rightarrow$ By one of two methods

1- By assuming different values for x in both sides.

2- Comparing the coefficients of both sides.

Ex: factorize $f(x) = \frac{x+1}{(x+2)(x-1)^3}$

$$f(x) = \frac{a}{(x+2)} + \frac{b}{(x-1)^3} + \frac{c}{(x-1)^2} + \frac{d}{x-1}$$

$$\frac{x+1}{(x+2)(x-1)^3} = \frac{a(x-1)^3 + b(x+2) + (x+2)(x-1) + d(x+2)(x-1)^2}{(x+2)(x-1)^3}$$

$$\cancel{a} = \lim_{x \rightarrow -2} \frac{x+1}{(x-1)^3} = \frac{-1}{-27} = \frac{1}{27}$$

$$b = \lim_{x \rightarrow 1} \frac{x+1}{x+2} = \frac{2}{3}$$

(2)

Put $x = -1$

$$0 = -8 \cdot \frac{1}{27} + \frac{2}{3} - 2c + 4d$$

$$0 = \frac{-8}{27} + \frac{2}{3} - 2c + 4d \rightarrow (1)$$

Put $x = 0$

$$1 = -\frac{1}{27} - \frac{2}{3} - 2c - 2d \rightarrow (2)$$

$$d = \dots \quad c = \dots$$

Case 3: Distinct complex root.

$$Q(x) = \frac{P_n(x)}{ax^2+bx+c} = \frac{ax+b_1}{ax^2+bx+c}$$

Case 4: Repeated complex root.

$$Q(x) = \frac{P_n(x)}{(ax^2+bx+c)^k} = \frac{a_1x+b_1}{(ax^2+bx+c)^k}$$

Ex: $f(x) = \frac{x+2}{(x-1)(x-2)^2(x^2+4)}$

$$f(x) = \frac{x+2}{(x-1)(x-2)^2(x^2+4)}$$

$$= \frac{a}{x-1} + \frac{b}{(x-2)^2} + \frac{cx+e}{x^2+4}$$

$$a = \frac{3}{5}$$

$$b = \frac{4}{8}$$

$$x+2 = a(x-2)^2(x^2+4) + b(x-1)(x^2+4) + c(x-1)(x-2)^2(x^2+4) + dx+e$$

Put: $x^2+4=0$

$$x^2 = -4$$

$$x+2 = (dx+e)(16+4x)$$

$$= 16dx + 16e - 16d + 4ex$$

(3)

$$C.O \quad x: \quad 1 = 16d + 4e$$

$$: \quad 2 = 16e - 16d$$

$$d: \dots$$

$$e = \dots$$

ثم نعود للحالة ستار للحصول على C

$$Ex: \quad f(x) = \frac{x^2 + 3}{(x^2 + 1)(x^2 + 2)(x^2 + 3)(x^2 + 4) \dots}$$

حول كل x^2 إلى y

$$Ex: \quad f(x) = \frac{3x^4 + 1}{x^2 + 2x} \quad x \quad x$$

$$= \frac{3 + x}{x^3 + 2x^2}$$

$$= \frac{a}{x^2} + \frac{b}{x} + \frac{c}{x+2}$$
